Report Overview

Recombinant Vector Vaccines are a type of vaccine that utilizes a modified, non-pathogenic virus or bacterium as a vector to deliver specific antigens from a target pathogen into the host's cells. This approach allows the host's immune system to recognize and respond to the introduced antigens, thereby generating an immune response against the pathogen. The vector used in these vaccines is typically engineered to be unable to replicate or cause disease, ensuring safety while still effectively presenting the antigens. Recombinant Vector Vaccines are advantageous for their ability to stimulate both humoral and cellular immunity, potentially offering long-lasting protection. They are also valuable in situations where traditional vaccines, such as inactivated or live-attenuated vaccines, are not feasible due to safety concerns or technical challenges. Examples of recombinant vector vaccines include those used for diseases like Ebola and COVID-19, where they have shown promise in clinical trials and real-world applications.
