## Abstracts

Regenerative Burning Device, often referred to as a Regenerative Thermal Oxidizer, is an advanced air pollution control technology designed to eliminate volatile organic compounds (VOCs), hazardous air pollutants (HAPs), and odorous emissions from industrial exhaust streams. It operates by passing polluted air through a series of heat exchange chambers filled with ceramic media that preheat the air before it enters a high-temperature combustion chamber. In the combustion chamber, typically operating between 800?1000?C, pollutants are oxidized into harmless carbon dioxide and water vapor. The treated air then passes through another ceramic bed, transferring its residual heat to incoming air, achieving thermal efficiencies up to 97%. This regenerative process not only ensures high destruction efficiency (up to 99%) of harmful emissions but also significantly reduces energy consumption. Regenerative Burning Devices are widely valued in industries requiring continuous emission control while minimizing operational costs and environmental impact.

The global Regenerative Burning Device market size was estimated at USD 615.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.80% during the forecast period.
