Report Overview:

DNA sequencing refers to the methods and technologies that used to determine the orders of nucleotide bases in a DNA molecule, namely adenine (A), guanine (G), cytosine (C) and thymine (T). DNA sequencing enables us to perform a thorough analysis of DNA because it provides us with the most basic information of all: the sequence of nucleotides. The knowledge of DNA sequences has formed the basis of basic biological researches and clinical genetic diagnosis. There are also numerous applied technology fields such as biotechnology, forensic science and biological systematics that are heavily dependent on the information generated through DNA sequencing. The rapid speed of sequencing attained with modern DNA sequencing technology has been instrumental in the sequencing of the human genome, in the Human Genome Project. Related projects, often by scientific collaboration across continents, have generated the complete DNA sequences the genomes of many animals, plants, and microorganisms. The Sanger method, also referred to as dideoxynucleotide sequencing or chain termination sequencing, is based on the use of dideoxynucleotide (ddNTP) in addition to the normal nucleotides (dNTP) found in DNA. Dideoxynucleotide are essentially the same as nucleotides except they contain a hydrogen group on the 3' carbon instead of a hydroxyl group (OH). These modified nucleotides, when integrated into a DNA sequence, prevent the addition of further nucleotides thus stop the elongation of the DNA chain. This occurs because a phosphodiester bond cannot form between the dideoxynucleotide and the next incoming nucleotide, and thus the DNA chain is terminated.

The Global Sangers Sequencing Service Market Size was estimated at USD 313.63 million in 2023 and is projected to reach USD 503.25 million by 2029, exhibiting a
