Abstracts

Semiconductor Photonic Integrated Circuit is a microchip that contains two or more photonic elements that form a functional circuit. The technology detects, generates, transmits and processes light. Photonic integrated circuits make use of photons (or particles of light) rather than electrons, which electronic integrated circuits make use of. The main difference between the two is that photonic integrated circuits provide functionality for information signals applied at wavelengths in the visible spectrum or near-infrared (850-1650 nm) light. The most commercially available material platform for photonic integrated circuits is indium phosphide (InP), which allows the integration of various optical active and passive functions on the same chip. The original example of a photonic integrated circuit was a simple 2-part distributed Bragg reflector (DBR) laser, consisting of two independently controlled device sections - a gain section and a DBR reflector section.

The global Semiconductor Photonic Integrated Circuit market size was estimated at USD 835.2 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 12.45% during the forecast period.
