Abstracts

The 2025 U.S. tariff policies introduce profound uncertainty into the global economic landscape. This report critically examines the implications of recent tariff adjustments and international strategic countermeasures on Silicon-Carbon Composite Anodes competitive dynamics, regional economic interdependencies, and supply chain reconfigurations. Silicon-Carbon Composite Anodes are advanced anode materials used in lithium-ion batteries, combining silicon (Si) particles or nanostructures with conductive carbon matrices such as graphite, carbon black, or amorphous carbon. Silicon offers a theoretical capacity of $\sim 4200 \text{ mAh/g}$ nearly ten times higher than traditional graphite anodes ($\sim 372 \text{ mAh/g}$) but suffers from severe volume expansion ($\sim 300\%$) during lithiation, which can cause particle cracking and capacity fading. The carbon matrix in composite anodes mitigates these issues by enhancing mechanical stability, buffering volumetric changes, and improving electrical conductivity. These composites are engineered in various morphologies (core-shell, yolk-shell, porous structures) to balance energy density, cycle life, and rate performance. Silicon-Carbon Composite Anodes are characterized by key parameters such as specific capacity (typically $500\text{--}1200 \text{ mAh/g}$), silicon content ($5\text{--}70 \text{ wt}\%$), and initial coulombic efficiency ($70\text{--}90\%$). Their particle size usually ranges from 50 nm to $1 \text{ }\mu\text{m}$ for silicon and $5\text{--}15 \text{ }\mu\text{m}$ for the composite, with BET surface areas between $5\text{--}100 \text{ m}^2/\text{g}$. Tap density falls in the range of $0.5\text{--}1.5 \text{ g/cm}^3$, impacting volumetric energy density. These anodes are engineered to reduce silicon's natural volume expansion ($\sim 300\%$) down to $30\text{--}100\%$ through structural designs like porous matrices or yolk-shell architectures. They offer improved electrical conductivity via integrated carbon materials and exhibit stable cycle retention above 80% after $300\text{--}1000$ cycles. Operating voltages generally span $0.01\text{--}1.0 \text{ V}$ vs Li/Li^+ , making them ideal for high-performance lithium-ion batteries.

The global Silicon-Carbon Composite Anodes market size was estimated at USD

1473.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 13.70% during the forecast period.
