Abstracts

A Single Detector Gamma Camera is a specialized medical imaging device used primarily in nuclear medicine to produce functional images of physiological processes by detecting gamma radiation emitted from radiopharmaceuticals administered to patients. This system consists of a single large-area sodium iodide scintillation crystal detector coupled to an array of photomultiplier tubes, which collectively convert gamma rays into light signals and subsequently into electrical pulses for image formation through techniques such as planar scintigraphy or dynamic studies. While largely supplanted by dual-head systems in many clinical settings due to their faster acquisition times and improved efficiency, single detector gamma cameras remain relevant in specific applications such as thyroid uptake studies, small organ imaging, and certain dynamic functional assessments where high sensitivity over a focused field of view is prioritized. Their operational principle relies on collimation to spatially localize gamma emissions, and they are often characterized by their versatility, relatively lower cost compared to multi-detector configurations, and continued utility in niche diagnostic and research contexts.

The global Single Detector Gamma Camera market size was estimated at USD 261.42 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.25% during the forecast period.
