### Report Overview

A single-detector gamma camera is a medical imaging device that uses gamma rays to produce images of the body. It consists of a detector, which is typically made of crystals such as sodium iodide or cesium iodide, and a collimator, which is a lead shield with small holes in it that allows only gamma rays coming from a specific direction to reach the detector. When a patient is injected with a radioactive tracer, the tracer emits gamma rays, which are detected by the gamma camera. The detector then converts the gamma rays into electrical signals, which are processed by a computer to produce an image of the area being examined. Single-detector gamma cameras are commonly used in nuclear medicine for a variety of diagnostic purposes, including detecting cancers, assessing organ function, and evaluating blood flow. They are also frequently used during surgery to help locate tumors and other abnormalities.
