Report Overview

Small interfering RNA (siRNA) is a form of genetic medicine that can silence or knock out any overexpressed genes in disease. It's also called short interfering RNA. These RNAs are widely used to assess the specific contributions of genes to a variety of cell phenotypes, including apoptosis, pancreatic beta cell signaling, cytokinesis, and cell differentiation. They are used to identify novel pathways and have a meaningful impact on the identification of targets for several diseases (such as AIDS, cancer and hepatitis) and cellular processes. The mechanism of action of siRNA involves introducing it into cells. siRNA sequences should be designed to match the short regions of the target gene. Small interfering RNAs are processed by the cell's own enzymes to eliminate the mRNA of the target gene, thereby preventing overexpression of the pathogenic gene. It is based on the natural response of cells when they detect genetic abnormalities or infections. It has some advantages over the different types of therapies currently available, such as target specificity, reduced secondary effects, and high specificity. The preclinical development duration of small interfering RNA compounds (about 15 to 24 months) is shorter than that of monoclonal antibodies (about 27 to 50 months) or other traditional small molecules (about 42 to 66 months). The shortening of preclinical stage is attributed to the rational design of RNA. The design includes mathematical algorithms assembled in software to select the most appropriate RNA sequence to silence specific genetic targets. They are usually more effective than other traditional medicines. siRNA therapy includes liposome-based systemic therapy and nanoparticle based systemic therapy. Liposome-based systems are associated with liver-targeted pharmacokinetics, which limits the therapeutic potential of siRNA therapy to other common liver diseases, such as hepatocellular carcinoma, hepatitis, and hypercholesterolemia.
