Report Overview

Spin-on carbon materials provide high transparency for improved overlay control and high thermal stability for compatibility in various integration flows.

Spin-on carbon (SOC) hardmasks are an increasingly key component of the micro-chip fabrication process. They are frequently used to improve the resists' selectivity to silicon during plasma etching. Furthermore, as chip architectures become increasingly complex the use of hardmasks to improve the aspect ratio of features in silicon is critical. In this context, the 'aspect ratio' is the ratio between the height of a feature on a silicon wafer and its width. For many emerging multi-layer chip architectures, such as tri-layer etch-stacks, a large height to width ratio is required to maintain small lateral features across multiple vertical layers.

In a tri-layer etch stack the bottom layer is typically thick amorphous carbon deposited by chemical vapor deposition (CVD). The challenges for CVD are high capital and running costs, particle defects, and the non-planarizing nature of the layer.
