Abstracts

Software-based full-disk encryption is a security mechanism that transparently encrypts all data on a storage device using an encryption engine installed at the operating system level. Its core is to dynamically encrypt disk sectors below the file system layer using software algorithms (such as AES-XTS and AES-CBC), ensuring that data is persisted in ciphertext form on the storage media. This technology verifies user credentials (password, token, or biometric) in a pre-boot authentication environment (such as an OS-independent encryption module) and uses a key derivation function to generate encryption keys. This decrypts disk metadata before the system loads to boot the operating system, thereby achieving data-at-rest security. A key difference between software FDE and hardware FDE (such as self-encrypting drives) is that software FDE relies on the host CPU to perform encryption operations, and key management is typically integrated into the operating system or third-party security software, enabling flexible policy configuration and compliance auditing.

The global Software-based Full-Disk Encryption market size was estimated at USD 2744.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 5.40% during the forecast period.
