Report Overview

Solar desalination uses solar radiation energy to remove salt and minerals from seawater through thermal conversion and physical separation processes to obtain fresh water. This device does not rely on fossil fuels and is a clean and renewable way of utilizing energy, which is of great significance to solving the problem of global water shortage. Solar desalination collects solar radiation energy through solar panels or collectors and converts it into heat or electricity. The collected heat or electric energy is used to drive the heating element, and the seawater is heated to a boiling state to generate water vapor. After the water vapor enters the condenser, it encounters cold air or cooling medium and condenses into liquid water, thereby realizing the desalination of seawater. The condensed fresh water is collected and stored in a water storage tank for subsequent use. According to the different energy utilization methods, solar desalination devices can be divided into two categories: passive and active. Passive solar desalination devices use solar energy to directly heat seawater, and achieve evaporation and condensation of seawater through natural convection and radiation heat dissipation, without the need for additional electric energy to drive. This type of device has a simple structure and low cost, but the water output is relatively low and is greatly affected by the weather. In addition to using solar energy to heat seawater, active solar desalination devices are also equipped with auxiliary equipment such as water pumps and heat exchangers, which can actively recover the latent heat released by steam during the condensation process, thereby increasing water production and efficiency. Although this type of device has a complex structure and high cost, it has a large water output and good stability.
