Abstracts

Solar radiation nowcasting refers to the prediction of solar power output over time horizons of tens to hundreds of minutes ahead of time. It is an important part of solar power forecasting, usually with a time resolution of 5 to 15 minutes, and updates as frequent as every minute. It mainly relies on satellite - derived solar radiation data, ground - based meteorological observation data, and data from irradiance sensors. These techniques are usually based on time - series processing of measurement data, including meteorological observations and power output measurements from a solar power facility. Methods such as autoregressive moving averages (ARMA, ARIMA, etc.) can be used to establish prediction models. With the development of technology, machine - learning - based methods are being more and more widely used. For example, some studies use improved grey - relational analysis methods to extract highly correlated external meteorological features, and combine them with models such as Informer to improve the accuracy of short - term forecasting. There are also research projects that use a custom Yolov8 model to detect clouds and the sun, and employ reinforcement learning to predict cloud trajectories for solar radiation nowcasting. Accurate solar radiation nowcasting is of great significance for the efficient operation of photovoltaic power plants and the stable operation of the power grid. It can help photovoltaic power plants optimize power generation scheduling, reduce the impact of solar power intermittency on the power grid, and at the same time, assist power grid operators in making more reasonable dispatch decisions to ensure the reliability and stability of power supply.

The global Solar Radiation Nowcasting market size was estimated at USD 2271.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 6.10% during the forecast period.
