Abstracts

Synthetic peptide vaccines represent fragments of protein antigen sequences, synthesizing specific B cell and T cell epitopes offer the potential to induce diseases neutralizing immuno response with completely synthetic structure. Now it is well established that short chain peptides can be used to mimic antigenic sites of viruses and thus can be used the basics for vaccines and development. Synthetic peptide vaccine is the most ideal and safe new vaccine, and it is also one of the main directions for the development of new vaccines for the prevention and control of infectious diseases and malignant tumors. Solid-phase peptide synthesis (SPPS) is a mature production technology for peptides that are now widely used. The basic principle of this technique is that in insoluble porous support, the amino acid derivative rapidly assembles the peptide chain by successive reaction. An important consideration in peptide production is the use of protecting groups to avoid unnecessary side reactions. In solid-phase peptide synthesis, the two commonly used protection schemes are Fmoc/tBu and Boc/Bzl. The former uses the N-terminus of the base-unstable Fmoc, and the deprotection required for this method is generally mild. Boc/Bzl is advantageous when it is desired to reduce the aggregation of peptides in the production of peptides. In addition, since Fmoc is unstable to bases, Boc/Bzl approach is a better choice when synthesizing base-sensitive moieties. For some longer peptides, microwave-related peptide synthesis is a good choice for producing peptides with low levels of racemization, while chemical ligation, fragment condensation, are also preferable method for producing long peptides.

The global Solid Phase Peptide Synthesis (SPPS) Vaccine market size was estimated at USD 115.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 7.40% during the forecast period.
