Report Overview

Sonar measuring instruments are electronic devices that use the propagation characteristics of sound waves underwater to complete underwater detection, positioning and communication tasks through electroacoustic conversion and information processing. It works by utilizing the propagation characteristics of sound waves in water, which is similar to the working principle of radar in air, but the medium is different. The sonar measuring instrument consists of two parts: the transmitting transducer and the receiving transducer. The transmitting transducer is responsible for transmitting sound waves, which is equivalent to a loudspeaker in the air; the receiving transducer is responsible for receiving sound waves reflected or radiated by the target, which is equivalent to a microphone (microphone or speaker) in the air. Sonar is divided into two types: active and passive. Active sonar actively transmits sound waves and receives echoes to determine the target parameters; passive sonar mainly receives the radiated noise generated by the target or the signal emitted by the underwater acoustic equipment to determine the direction of the target.
