Abstracts

Special photoinitiators for photoresists are compounds that absorb light and initiate the polymerization process essential for the creation of microstructures in photoresist materials used in semiconductor manufacturing and other high-precision applications. These photoinitiators are designed to be sensitive to specific wavelengths of light, typically in the UV or deep-UV range, to ensure precise patterning during photolithography. Common types of photoinitiators include onium salts (like iodonium and sulfonium salts) and acylphosphine oxides, which are chosen based on their ability to produce strong acid or radical species upon exposure to light, thereby catalyzing the crosslinking or decomposition of the photoresist. The choice of photoinitiator is crucial for achieving high resolution, sensitivity, and stability in the final patterned structures, making them integral to the production of integrated circuits, microelectromechanical systems (MEMS), and other nanotechnology applications.

The global Special Photoinitiator For Photoresist market size was estimated at USD 450.25 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 6.45% during the forecast period.
