Abstracts

Spent fuel refers to the part of nuclear fuel discharged from the pressure vessel of a nuclear power plant after a cycle of use. It contains unburned uranium-235 and newly generated fissile material plutonium-239, as well as fission products such as strontium-90, cesium-137, and technetium-99. Although the nuclear reaction can no longer be maintained due to the reduction of uranium content, it still has a large amount of decay heat and radioactivity. All nuclear power plant reactors will produce spent fuel. With the development of nuclear power, more and more spent fuel will inevitably be produced. Countries around the world have the following three strategies for spent fuel management: reprocessing; deep geological direct disposal; intermediate storage. Regardless of the plan, spent fuel needs to be stored. The International Atomic Energy Agency (IAEA) has also proposed in its many publications that spent fuel storage is an important stage in the nuclear fuel cycle.

The global Spent Fuel Recycling Storage Equipment market size was estimated at USD 1896.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 7.50% during the forecast period.
