Abstracts

Subcutaneous immunotherapy (SCIT), commonly known as allergy shots, is a long-term medical treatment designed to desensitize individuals to specific allergens by administering gradually increasing doses of purified allergen extracts under the skin. This treatment modality operates on the principle of modulating the immune system, shifting the body's response from an allergic reaction to one of tolerance, thereby reducing symptoms such as sneezing, itching, and respiratory distress associated with allergic rhinitis, asthma, or insect venom allergies. The therapy typically involves two phases: an initial build-up phase with frequent injections to reach a target maintenance dose, followed by a longer-term maintenance phase where injections are administered less frequently, often over several years. SCIT is distinct from sublingual immunotherapy (SLIT), as it requires clinical administration under medical supervision due to the risk of systemic reactions, including anaphylaxis. It is considered a disease-modifying treatment, offering the potential for sustained symptom relief even after discontinuation, and is supported by decades of clinical evidence demonstrating efficacy in reducing allergic sensitivity and improving quality of life for patients with IgE-mediated allergic conditions.

The global Subcutaneous Immunotherapy market size was estimated at USD 1250.0 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 11.50% during the forecast period.
