Abstracts

Superconducting Magnetic Energy Storage (SMES) store energy in the magnetic field created by the flow of direct current in a superconducting coil which has been cryogenically cooled to a temperature below its superconducting critical temperature. A typical SMES system includes three parts: superconducting coil, power conditioning system and cryogenically cooled refrigerator. Once the superconducting coil is charged, the current will not decay and the magnetic energy can be stored indefinitely. As electrical grids worldwide age, SMES systems are being adopted to improve reliability and prevent outages in existing infrastructure. Increasing demand for high-quality power, especially in industries like healthcare, data centers, and manufacturing, drives the need for SMES systems that can mitigate voltage sags, spikes, and harmonics. Governments and organizations worldwide are focusing on achieving net-zero emissions, which promotes the adoption of renewable energy technologies. SMES systems address the intermittency of renewable energy sources by storing excess power during peak production and discharging it when generation is low. Progress in HTS materials reduces cooling requirements and costs, making SMES systems more viable for commercial applications. Innovations in superconducting materials and cryogenics allow for smaller, more efficient SMES systems suitable for diverse applications. Technological advancements have led to near-perfect efficiency in energy storage and retrieval, making SMES a preferred option for specific high-performance applications.

The global Superconducting Magnetic Energy Storage (SMES) market size was estimated at USD 82.3 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 8.90% during the forecast period.
