Report Overview

Reverse osmosis water purifiers are widely used in the water treatment industry as they are recognised as the most effective water purification system, effectively removing suspended particles, colloids, rust, sediment, heavy metals, residual chlorine, organic matter, bacteria, viruses etc., reducing water hardness and improving taste. However, most of these reverse osmosis water purifiers have to be configured with water storage tanks due to insufficient flow, which are large and inconvenient to install. In addition, pure water in the tank for a long time with the internal rubber air bag contact, making the pure water with rubber smell, taste greatly reduced. When the pure water is not used for a long time, microorganisms multiply in the storage tank, which can also easily cause secondary pollution. Therefore, no tank design is the inevitable trend in the development of reverse osmosis water purifier industry. Currently, tankless reverse osmosis water purifiers on the market usually use a large flux of reverse osmosis membrane (RO membrane) or several small flux reverse osmosis membranes in parallel to solve the problem of insufficient water flow. These products mostly use double opening and closing switches to control the opening or closing of the source water inlet and pure water outlet at the same time, while the flowmeter set in the pipeline to determine the status of the double opening and closing switches, when the double opening and closing switches open or close, the flowmeter will pass this signal to the controller, the controller issued instructions to control the work of the machine, thus achieving the purpose of using double opening and closing switches to indirectly control the work of the machine.
