### Report Overview:

Thin wafer handling will enjoy increased importance in the coming years, but as chips get thinner and wafer diameter increases, thinning/handling procedures are required. This implies development in wafer thinning, wafer dicing and wafer temporary bonding. Temporary bonding implies know-how in process and chemistry, and an understanding of the final application requirements. Temporary bonding is a complex technology, requiring an interface material (sometimes called the “Magic” material) that is strong enough to withstand post-processing but which can be easily removed afterwards. As the main concern for temporary bonding materials (wax, tape or glue) is temperature stability, the material must be strong enough to withstand processing steps (metallization, etching, grinding). Another issue is the choice of carrier material. Carrier lifetime depends on its capability to withstand steps such as grinding, etc., and carrier lifetime should be at least tens of times.

The Global Temporary Wafer Debonding System Market Size was estimated at USD 340.69 million in 2023 and is projected to reach USD 552.76 million by 2029, exhibiting a CAGR of 8.40% during the forecast period.
