Report Overview

Thermal interface materials (TIMs) are purpose-built substances or structures that reduce the thermal contact resistance between a heat source (e.g., CPUs/GPUs, power modules, batteries) and a heat spreader or heat sink by displacing air in microscopic surface asperities with a thermally conductive medium. They span greases, pads, phase-change films, gap fillers, adhesives/epoxies, metal foils/solders, and advanced carbon-based laminates, and are engineered for a balance of conductivity (W/m²K), conformability (to fill gaps and tolerate stack-up/warpage), dielectric strength, pump-out/bleed resistance, reworkability, and reliability across wide temperature and humidity ranges. As device power densities climb and form factors shrink, TIMs become a critical reliability component that determines junction-to-ambient thermal paths and, consequently, performance throttling margins and lifetime.

The global market for thermal interface materials in 2024 is estimated at around USD 1.42 billion, with a projected CAGR of about 5.78% from 2024 to 2033. Growth is driven by rising demand for compact high-performance electronics, the rapid expansion of electric vehicles, the growth of data centers and 5G infrastructure, and increasing adoption in renewable energy systems and advanced medical devices.
