### Report Overview

Thermally-Modified Timber (TMT) is referring to a wood which is modified by a controlled pyrolysis process. In this process, the wood is heated up to 180°Celsius, in the absence of oxygen. This process helps the chemical to change its cell structure of cell wall components in the wood in order to increase its durability. During this process, the low oxygen content prevents the wood from burning even at the high temperature. There are five thermal modification processes: Thermowood, Retification Process, Les Bois Perdure, Plato Process, and Oil Heat Treatment.

Thermal modification uses heat to remove organic compounds from the wood cells, so it will not absorb water, expand, contract, or provide nourishment for insects or fungi. The high heat produces a naturally durable wood that is permanently resistant to water, insects, and decay. Because the wood is not absorbing chemicals to be treated, but rather removing moisture, the wood is lightweight.
