Abstracts

A thermosonic ball bonder is a specialized semiconductor assembly machine used in the microelectronics industry to create electrical connections between integrated circuits (ICs) and their packaging substrates or lead frames through a hybrid bonding process that combines heat, ultrasonic energy, and mechanical force. This equipment forms a gold or copper wire into a ball at one end using an electric spark (electronic flame-off, or EFO), then presses it onto the bond pad of the semiconductor die while simultaneously applying ultrasonic vibration and controlled thermal energy (typically 150?250?C) to create a metallurgical weld without melting the wire entirely. The process is highly valued for producing reliable, fine-pitch interconnects with minimal mechanical stress on delicate die structures, making it essential in manufacturing advanced devices such as microprocessors, memory chips, sensors, and RF components where precision, electrical performance, and thermal stability are critical. It represents a key step in wire bonding?the dominant method for chip interconnection?and is distinguished from purely thermal (thermocompression) or ultrasonic-only techniques by its ability to achieve strong bonds at lower temperatures and with shorter cycle times, thereby improving throughput and reducing the risk of damaging heat-sensitive components.

The global Thermosonic Ball Bonder market size was estimated at USD 450.25 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.80% during the forecast period.
