Abstracts

A Time-of-Flight (ToF) Distance Image Sensor is a specialized type of imaging device that measures the distance to objects in its field of view by calculating the time it takes for emitted light (typically infrared) to reflect back to the sensor, generating a depth map or 3D point cloud rather than a traditional 2D color image. These sensors operate by emitting modulated light signals and analyzing the phase shift or time delay of the returning signals, enabling precise, real-time distance measurements for each pixel. They are distinguished from other depth-sensing technologies, such as structured light or stereo vision, by their ability to function effectively in varying lighting conditions, provide high frame rates, and offer relatively long-range capabilities. ToF sensors are integral to applications requiring spatial awareness, including augmented reality, robotics, automotive safety systems, gesture recognition, and industrial automation, where accurate, rapid depth perception is critical.

The global ToF Distance Image Sensor market size was estimated at USD 980.5 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 12.30% during the forecast period.
