Abstracts

A transistorized oscillator is an electronic circuit that utilizes transistors as the active component to generate a periodic, oscillating electronic signal?such as a sine wave, square wave, or sawtooth wave?without requiring an external input signal once initiated. These devices operate based on the principle of positive feedback, where a portion of the output signal is fed back to the input in phase to sustain oscillations at a specific frequency determined by the circuit?s reactive components (such as inductors and capacitors). Known for their compact size, efficiency, reliability, and tunability, transistorized oscillators are fundamental building blocks in a wide range of applications, including radio transmitters and receivers, signal generators, clock circuits in digital devices, sensors, and test and measurement equipment, effectively replacing older vacuum tube-based designs in most modern electronic systems.

The global Transistorized Oscillator market size was estimated at USD 1053.42 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 4.75% during the forecast period.
