Abstracts

Alpha 1-antitrypsin deficiency (AATD) treatment is a specialized therapeutic area focused on addressing the genetic disorder characterized by low levels of alpha 1-antitrypsin (A1AT), a protein produced in the liver that protects the lungs from neutrophil elastase—an enzyme that breaks down foreign organisms and damaged tissues. The deficiency leads to uncontrolled elastase activity, resulting in progressive lung damage (emphysema) and, in some cases, liver disease due to accumulation of misfolded A1AT protein in hepatocytes. Current treatments primarily involve augmentation therapy, which entails intravenous infusions of purified A1AT derived from human plasma to increase serum levels and slow lung tissue degradation, alongside supportive measures such as bronchodilators, corticosteroids, antibiotics for infections, and lifestyle modifications like smoking cessation. For liver manifestations, management may include monitoring, addressing complications, and in severe cases, liver transplantation. Emerging therapies in development focus on novel approaches, including recombinant A1AT, gene therapies aimed at enabling the body to produce functional protein, and small molecule correctors designed to improve the folding and secretion of mutant A1AT, offering potential alternatives to lifelong infusion-based regimens.
