Report Overview

The adjustable optical power wavelength division multiplexer is a device used in optical communication systems to achieve multiplexing and demultiplexing of optical signals. Normally, multiple optical signals need to be multiplexed in an optical communication system to improve the utilization of optical fibers. Traditional wavelength division multiplexers are usually fixed wavelength and can only multiplex optical signals of specific wavelengths. The tunable optical power wavelength division multiplexer has the characteristics of adjustable wavelength, and can flexibly select the wavelengths for multiplexing and demultiplexing according to needs. Tunable optical power wavelength division multiplexers usually consist of two main parts: one is an optical path multiplexer, which is used to multiplex multiple input optical signals onto the same optical fiber; the other is an optical path demultiplexer, which uses To demultiplex the multiplexed optical signals to their respective output ports. In the process of multiplexing and demultiplexing, the tunable optical power wavelength division multiplexer realizes the selection and distribution of optical signals of different wavelengths by adjusting the working wavelength of the wavelength selector or filter.
