Abstracts

When the ultrasonic wave acts on the thermoplastic contact surface, tens of thousands of high-frequency vibrations per second will be generated. This kind of high-frequency vibration with a certain amplitude will transmit the ultrasonic energy to the welding area through the upper weldment. Since the welding area is two The acoustic resistance at the interface of two welds is large, so local high temperature will be generated. And because of the poor thermal conductivity of the plastic, it cannot be dissipated in time for a while, and it gathers in the welding area, causing the contact surface of the two plastics to melt rapidly, and after a certain pressure is added, it is fused into one. When the ultrasonic wave stops working, let the pressure continue for a few seconds to make it solidify and form, thus forming a strong molecular chain to achieve the purpose of welding, and the welding strength can be close to the strength of the raw material. The quality of ultrasonic plastic welding depends on three factors: the amplitude of the transducer horn, the applied pressure and the welding time. The welding time and the pressure of the horn can be adjusted, and the amplitude is determined by the transducer and the horn. There is an appropriate value for the interaction of these three quantities. When the energy exceeds the appropriate value, the melting amount of the plastic will be large, and the weld is easy to deform; if the energy is small, it will not be easy to weld firmly, and the applied pressure should not be too large. This optimal pressure is the product of the side length of the welded part and the optimal pressure per 1mm of the edge.

The global Ultrasonic Plastic Welding Technology market size was estimated at USD 431.05 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 3.00% during the forecast period.
