Abstracts

Unbuffered DIMM (UDIMM) is a type of memory module commonly used in desktop computers, entry-level servers, and workstations, characterized by its lack of a register or buffer between the memory controller and the DRAM chips, which allows for lower latency and reduced cost compared to registered (RDIMM) or load-reduced (LRDIMM) modules, but at the expense of limited capacity per module and higher electrical load on the memory controller, making it suitable for systems where performance per module is prioritized over maximum memory scalability or stability under heavy loads.
