Report Overview

Underwater acoustic recorder is an instrument used to record sound in underwater environments. It is usually used for marine biology, oceanography and environmental research to monitor the sound emitted by marine animals such as whales, dolphins and fish. The recorder usually consists of a hydrophone (an underwater microphone) and a data storage device (such as a hard disk drive or flash memory). The hydrophone is designed to pick up the sound in the water and convert it into an electrical signal, and then record it on the data storage device. Underwater acoustic recorders are typically deployed in the ocean for a long period of time, ranging from a few days to several months. They are usually anchored to the seabed or connected to buoys, designed to withstand harsh underwater environments. The data recorded by the recorder can be analyzed to study the behavior and communication of marine animals, as well as to monitor the impact of human activities on the marine environment. For example, changes in the sounds emitted by marine animals can provide insights into their behavior, migration patterns, and changes in population size. These data can also be used to study underwater noise pollution, which may have negative impacts on marine life.
