Report Overview

Ultraviolet (UV) sanitizing units are used in many water purification systems to control bacteria and have certain applications in animal drinking water systems. UV units can be effective water treatment tools, but it is important to recognize what UV can do, what its limitations are, and what maintenance is required.

The presence of ultraviolet or UV energy in the electromagnetic spectrum between visible light and x-rays can be described as 'invisible radiation.' In order to kill microbes, ultraviolet light actually has to strike the cells. Ultraviolet light can penetrate the outer cell membrane, pass through the cell body, and destroy the cell's DNA to prevent reproduction. UV treatment does not change the chemical properties of the water; Nothing is added except energy. The sterilized microorganism is not removed from the water. Ultraviolet disinfection does not remove organic matter, inorganic matter or particles dissolved in water.

The degree of passivation of UV radiation is directly related to the UV dose to water. The dose is the product of the UV intensity and the exposure time, measured in microwatt seconds per second per square centimeter (ws/cm^2). The following table lists the dosage requirements of microorganisms for the destruction of commonly used drugs. Most UV units are designed to provide a dose greater than 30,000 ws/cm^2 after a continuous operating year. Note that UV does not effectively disinfect certain microorganisms (most molds, protozoa, and cysts of giardia lamblia and cryptosporidium) because they require higher doses.
