Abstracts

A vapor cycle system is a type of refrigeration system that uses the vapor compression cycle to transfer heat from one location to another. It is commonly used in air conditioning systems and refrigerators. The vapor cycle system consists of four main components: a compressor, a condenser, an expansion valve, and an evaporator. The refrigerant, which is typically a fluid with low boiling point, circulates through these components to absorb heat from the desired location and release it elsewhere. The process starts with the compressor, which compresses the low-pressure refrigerant vapor into a high-pressure vapor. This high-pressure vapor then flows into the condenser, where it releases heat to the surroundings and condenses into a high-pressure liquid. The high-pressure liquid then passes through the expansion valve, which reduces its pressure and temperature. This low-pressure liquid then enters the evaporator, where it absorbs heat from the desired location (e.g., a room or a refrigerator) and evaporates into a low-pressure vapor. The low-pressure vapor is then drawn back into the compressor, and the cycle repeats. This continuous circulation of the refrigerant allows the system to transfer heat from a lower temperature location (evaporator) to a higher temperature location (condenser).

The global Vapor Cycle System market size was estimated at USD 14290.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 3.60% during the forecast period.
