Report Overview

Vascular closure devices are medical devices used to achieve hemostasis of the small hole in the artery after a cardiovascular procedure of endovascular surgery requiring a catheterization. The devices seal the puncture site in an artery (the arteriotomy) through mechanical means rather than relying on the body's natural clotting response.

Vascular Closure Devices were introduced in the early 1990s in an effort to reduce the time to hemostasis, enable early ambulation and improve patient comfort. Initially, devices focused on technologies involving a suture or a collagen plug. These technologies are effective at closing the hole; however, they often leave an intravascular component in the artery, which can cause complications. In addition, these technologies failed to accurately address patient pain. More recent methods to close the hole involve the use of novel materials that dissolve over a short period of time, such as polyethylene glycol found in the Mynx vascular closure device. These technologies incorporate a more gentle deployment of the material to the outside of the artery and avoid the use of intravascular components, leaving nothing behind in the artery and consequently improving patient comfort.

Generally, there are two types of vascular closure devices: active and passive, in this report, vascular closure devices refer to active vascular closure devices.

Global Vascular Closure Devices (VCDS) key players include Abbott Laboratories, St. Jude Medical, Cardinal Health, etc.
