Abstracts

Vertical electroless copper refers to a specialized chemical deposition process used primarily in the printed circuit board (PCB) industry to metallize the walls of through-holes, microvias, and other vertical structures, ensuring reliable electrical connectivity between different layers of multilayer boards. This autocatalytic method deposits a uniform, adherent copper layer without external electrical current, relying instead on chemical reduction in a controlled bath containing copper ions, complexing agents, reducing agents, and stabilizers. The process is critical for creating high-reliability interconnects in advanced PCBs, particularly as board designs trend toward higher density, finer features, and increased layer counts, with performance heavily dependent on parameters such as bath composition, temperature, agitation, and surface preparation to achieve optimal conductivity, thickness uniformity, and adhesion while minimizing defects like voids or nodules.

The global Vertical Electroless Copper market size was estimated at USD 620.0 million in 2024 and is projected to grow at a compound annual growth rate (CAGR) of 6.50% during the forecast period.
