## Abstracts

A vessel-mounted ADCP relies on the same principles as a stationary ADCP, producing a profile of the currents between the vessel and the seabed. However, vessel-mounted ADCPs encounter an extra layer of complication while measuring, because the vessel on which they are mounted is moving. This means the ADCP will have to account for the speed and direction of the vessel when determining the velocity of the currents beneath it. Thankfully, an ADCP can also calculate the speed of the vessel over the seabed, using a technique called "bottom tracking." To perform bottom tracking, the ADCP measures the Doppler shift of a ping that bounces off the seabed, rather than scatterers in the water like with current measurements. This effectively measures the speed of the vessel relative to the sea floor.

The global Vessel-mounted ADCP market size was estimated at USD 63.8 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 5.40% during the forecast period.
