Report Overview

Viral vector is a tool that molecular biologists use to deliver genetic material into cells. This process is performed using viruses as vectors of the genetic material to be transferred into host cells. The delivery of genes by a vector is called transduction while the host cells are called transduced after an infection by viral vectors. Viral vector purification is the process by which viral particles are isolated from the host cell in which it has grown. This is done after the process of gene delivery in the host cell has occurred. The common methods of viral vector purification are chromatography and centrifugation.
