Abstracts

A virtual firewall (VF) is a network firewall service or appliance running entirely within a virtualized environment and which provides the usual packet filtering and monitoring provided via a physical network firewall. The VF can be realized as a traditional software firewall on a guest virtual machine already running, a purpose-built virtual security appliance designed with virtual network security in mind, a virtual switch with additional security capabilities, or a managed kernel process running within the host hypervisor. While a boon for speeding up innovation and lowering computing costs, virtual environments also come with a growing number of security and compliance risks not found in traditional data centers. New kinds of attacks that bypass standard perimeter security often feast upon decentralized infrastructures where applications, data and workloads are deployed from multiple endpoints rather than a single dedicated resource, making comprehensive visibility and security difficult to attain. The speed with which users now expect virtualized environments to provide services is another security concern. Security professionals must juggle DevOps speed with security challenges that now span dispersed environments. The right next-generation virtual firewall can help to provide a consistent network security posture across your IT environment, including private clouds, public clouds and branch locations. Find more information on the core uses cases in 3 Virtual Firewall Use Cases.
