Abstracts

The 2025 U.S. tariff policies introduce profound uncertainty into the global economic landscape. This report critically examines the implications of recent tariff adjustments and international strategic countermeasures on Vision-based Tactile Sensor competitive dynamics, regional economic interdependencies, and supply chain reconfigurations. In 2024, global Vision-based Tactile Sensor production reached approximately 254 k units with an average global market price of around US\$350 per unit. Single-line annual production capacity averages 6k units with a gross margin of approximately 30-35%. The upstream of the visuotactile sensor industry encompasses critical raw materials such as optical components, elastic materials, and microelectronic modules, which are primarily concentrated in the fields of precision manufacturing and materials science. The midstream involves the research, development, and manufacturing of sensors, where the consumption of products is closely related to downstream applications. For instance, in the robotics industry, each high-end robot averages a consumption of approximately 5-10 visuotactile sensors, accounting for over 20% of the total. The downstream primarily includes sectors such as robotics, prosthetics, and virtual reality, with the consumption of visuotactile sensors continuously increasing as technology matures and the market expands. Vision-based Tactile Sensor is a sensing method that integrates optical imaging with tactile perception. Its core principle is to capture the microscopic deformation of elastic materials when they contact objects and convert it into high-resolution tactile information. The principle of the vision-based tactile sensor is to use a camera to capture the subtle deformation of the elastic material when it contacts the object, and then convert these changes into a high-definition "tactile photo", observing the deformation of the soft layer through the camera to "feel" the force, texture and sliding. Unlike traditional pressure sensors, tactile sensors can simultaneously "feel" the hardness, texture, and even sliding tendency of objects. This high-fidelity tactile information can help robots more accurately "understand" the

characteristics of objects and perform fine operations like humans. Vision-based tactile sensors use optical principles to perceive multi-dimensional information without electrical interference, but real-time feedback and flexible response are limited, susceptible to temperature effects and have a large volume.

The global Vision-based Tactile Sensor market size was estimated at USD 89.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 13.00% during the forecast period.
