Abstracts

The 2025 U.S. tariff policies introduce profound uncertainty into the global economic landscape. This report critically examines the implications of recent tariff adjustments and international strategic countermeasures on Weld-on Anode competitive dynamics, regional economic interdependencies, and supply chain reconfigurations. A weld-on anode is a type of sacrificial anode specifically designed to be directly welded onto the metal structure it aims to protect, such as pipelines, storage tanks, ship hulls, or offshore platforms, to provide cathodic protection against corrosion. Unlike other anodes that may be attached via bolts, clamps, or adhesives, weld-on anodes form a permanent and robust metallurgical bond with the base metal through welding. This installation method ensures excellent electrical conductivity between the anode and the structure, enabling efficient current flow to prevent the structure from acting as the anode in a corrosion cell. Typically made from materials like zinc, aluminum, or magnesium alloys, which are more electroactive than the protected metal, weld-on anodes sacrificially corrode themselves over time to divert corrosion away from the structure. Their design often includes a welded tab, strap, or pad that facilitates secure attachment while minimizing heat damage to the anode material during the welding process, making them suitable for applications where a strong, durable connection is critical, especially in harsh environments like marine, industrial, or buried infrastructure.

The global Weld-on Anode market size was estimated at USD 327.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.50% during the forecast period.
