### Report Overview

Glycosaminoglycans (GAGs) are a group of complex, long-chained polysaccharides that play a crucial role in various biological processes. They are composed of repeating disaccharide units, which consist of a hexosamine (either glucosamine or galactosamine) and a uronic acid (either glucuronic acid or iduronic acid). GAGs are an essential component of extracellular matrix, proteoglycans, and cell surfaces, where they contribute to tissue hydration, cell signaling, and structural integrity. There are several types of GAGs, including heparan sulfate, heparin, chondroitin sulfate, dermatan sulfate, keratan sulfate, and hyaluronic acid. Each type has unique properties and functions, such as heparin's role in blood clotting and hyaluronic acid's involvement in joint lubrication and skin hydration. GAGs are synthesized by specific enzymes and can be modified post-translationally, which further influences their biological activities.
