Report Overview

An Interatrial Shunt Device is a medical device designed to create a controlled opening or shunt between the left and right atria of the heart. This device is primarily used in the treatment of heart failure, specifically in patients with left ventricular dysfunction and pulmonary hypertension. The primary function of the Interatrial Shunt Device is to facilitate the controlled decompression of elevated left atrial pressure by allowing a portion of the blood to flow from the left atrium to the right atrium. This helps to reduce the strain on the left ventricle and improve cardiac output. The device is typically implanted using minimally invasive techniques, such as catheterization, and is designed to be adjustable to accommodate varying patient needs. The use of an Interatrial Shunt Device aims to provide symptom relief, improve quality of life, and potentially reduce the need for more invasive procedures or heart transplantation in eligible patients.
