### Report Overview

Intravitreal fluid tamponades are specialized medical solutions or gases injected into the vitreous cavity of the eye to maintain retinal attachment and stabilize the eye's internal structure following vitreoretinal surgeries, such as retinal detachment repairs or macular hole treatments. These tamponades function by applying consistent pressure to the retina, preventing fluid accumulation and promoting healing. Common types include silicone oil, perfluorocarbon liquids (PFCLs), and expansile gases like sulfur hexafluoride (SF<sub>6</sub>) or perfluoropropane (C<sub>3</sub>F<sub>8</sub>). The choice of tamponade depends on factors such as surgical complexity, duration of retinal support needed, and patient-specific conditions. The market for these products is driven by the increasing prevalence of retinal disorders, advancements in ophthalmic surgical techniques, and the growing aging population susceptible to vision-related conditions. However, adoption is influenced by factors like postoperative complications, the need for secondary removal procedures (particularly with silicone oil), and cost constraints in developing regions. Innovations in long-acting and biodegradable tamponade agents are emerging as key trends, alongside rising demand for minimally invasive retinal treatments.
