Report Overview

A latching signal relay is an electrical relay that has two stable states and can be held in one of them without a constant control signal. The characteristic of the blocking signal relay is that under the action of the control signal, it switches to a state and remains in this state until it is changed by the opposite control signal. Latching signal relays usually consist of a control coil and multiple contacts. The control coil receives a control signal, and when a control signal is received, it switches the contacts to a stable state and maintains that state. In other words, the contacts of the latching signal relay remain in the so-called "latching" state and do not switch to the other state until an opposing control signal is received. Typical applications for latching signal relays include circuit switching, memory functions, and state retention. Because latching signal relays can maintain their state when the control signal is lost, they are often used in applications that need to maintain their state after a power interruption or loss of control signal. They can also be used for timing control, circuit locking and circuit reset.
