Report Overview

Logistic Regression Models are a type of statistical model used in predictive analytics and machine learning to analyze a dataset in which there are one or more independent variables that determine an outcome. The outcome is measured with a dichotomous variable, meaning it has only two possible outcomes, such as pass/fail, win/lose, alive/dead or healthy/sick. Logistic regression is used to describe data and to explain the relationship between one dependent binary variable and one or more nominal, ordinal, interval, or ratio-level independent variables. It is particularly useful for predicting probabilities and is widely applied in fields such as finance, social sciences, and healthcare for risk assessment, fraud detection, and diagnosis. The model estimates the probability of the occurrence of an event by fitting data to a logistic curve, which can then be used to classify new observations into one of the two categories.
