Report Overview

NF-kB inhibitors are a class of pharmaceutical compounds designed to target and suppress the activity of the nuclear factor kappa-light-chain-enhancer of activated B cells (NF-kB) pathway. NF-kB is a protein complex that controls transcription of DNA, cytokine production, and cell survival, playing a crucial role in immune and inflammatory responses. By inhibiting NF-kB, these inhibitors can potentially reduce inflammation and treat various diseases characterized by chronic inflammation, such as autoimmune disorders, cancer, and neurodegenerative diseases. NF-kB inhibitors can be small molecules or biologics, and they work by blocking the activation, nuclear translocation, or DNA binding of NF-kB, thereby preventing the expression of pro-inflammatory genes and promoting a more balanced immune response.
