Report Overview

Non-fibered embolization coils are medical devices used in minimally invasive procedures to block blood flow in targeted vessels, typically for treating aneurysms, arteriovenous malformations (AVMs), or traumatic bleeding. Unlike fibered coils, which incorporate synthetic fibers to promote thrombosis, non-fibered coils rely solely on their mechanical structure—often platinum or other biocompatible metals—to induce clotting by disrupting blood flow and encouraging natural coagulation. These coils are deployed via catheter-based delivery systems, allowing precise placement in vascular abnormalities without open surgery. Their primary applications include neurovascular interventions, peripheral embolization, and certain oncological treatments where controlled vessel occlusion is required. The design variations include helical, complex-shaped, or detachable coils, offering flexibility based on procedural needs. As a critical tool in interventional radiology and endovascular surgery, non-fibered embolization coils balance efficacy with reduced inflammatory response compared to fibered alternatives, making them suitable for sensitive anatomical regions.
