Report Overview

Palbociclib is a targeted cancer therapy medication, classified as a cyclin-dependent kinase (CDK) inhibitor. It works by inhibiting the activity of CDK 4/6 proteins, which are crucial in promoting the growth of cancer cells, particularly in breast cancer. By blocking these proteins, Palbociclib hinders the progression of cancer cells through the cell cycle, ultimately preventing their proliferation. This medication is typically used in combination with other cancer treatments, such as hormone therapy, to treat certain types of metastatic breast cancer. Palbociclib is administered orally and is often prescribed for patients with hormone receptor-positive, human epidermal growth factor receptor 2 (HER2)-negative metastatic breast cancer. It is important to note that Palbociclib is not a cure for cancer, but it can help manage the disease and potentially extend the time before the cancer progresses.
