### Report Overview

Photocatalytic powder is a specialized material composed of semiconductor nanoparticles, typically titanium dioxide (TiO<sub>2</sub>) or modified variants, which harness light energy (usually UV or visible light) to accelerate chemical reactions, particularly oxidation processes that break down organic pollutants, bacteria, and volatile organic compounds (VOCs). These powders are engineered to exhibit high surface area and reactivity, making them effective in applications such as air and water purification, self-cleaning surfaces, and antimicrobial coatings. The photocatalytic effect is driven by the generation of electron-hole pairs upon light absorption, which then react with environmental molecules to produce reactive oxygen species capable of decomposing contaminants. Advances in doping techniques and nanostructuring have enhanced their efficiency under visible light, broadening their commercial viability beyond traditional UV-dependent systems. The material's performance is measured by factors like photocatalytic activity, stability, and reusability, with ongoing research focused on improving cost-effectiveness and scalability for industrial use.
