Report Overview

A rebreather is an aqualung that partially purifies diver's exhaled breath using carbon dioxide, mixed with more oxygen, which can be breathed again by the diver. Absorption of the carbon dioxide from user's exhaled breath permits the rebreathing of the substantially unused oxygen content. Oxygen is added to replenish the amount metabolized by the user. This differs from an open-circuit breathing apparatus, where the exhaled gas is discharged directly into the environment. Rebreather technology is majorly used where supply of oxygen for breathing is limited such as underwater or in space. Also, it has applications in firefighting, mine rescue and high-altitude operations, where the air is contaminated with toxic or hypoxic gases such as helium diluent or anesthetic gases.
