Abstracts

Wafer fabs continually face challenges in manufacturing semiconductor devices because the devices continue to get tinier and more complicated. Integrated circuits continue to increase in circuit density. Trends in chip design and materials, such as using die attach films and wafers as thin as 50 μ m, add to the complexity of manufacturing. In fabrication processes, wafer dicing plays an early and critical role in the quality of the final product. For silicon wafers less than 100 μ m thick, laser ablation offers an alternative to the blade technique, which is too powerful for the delicate thin wafers. However, laser ablation has its own problems. Vaporizing the wafer with a laser along the dicing path creates molten debris and microcracks. The debris deposited on the surface of the wafer is difficult to clean up, and the cracks result in chips with lower strength. In contrast, stealth dicing does not generate the problems brought on by either the blade or laser ablation techniques. With stealth dicing, there is no chipping or debris, which eliminates the need for a cleanup process. It also reduces the amount of wasted wafer because of its very narrow dicing path, offering space on the wafer for more chips and higher production yield. Also, the technique does not cause heat damage because the laser cuts below the surface of the wafer; this contributes to rendering the chips more resistant to breakage.

The global Silicon Wafer Laser Dicing Machine market size was estimated at USD 280.0 million in 2025 and is projected to grow at a compound annual growth rate (CAGR) of 4.50% during the forecast period.
